Pandas Cheat Sheet

Note: df - A pandas DataFrame object, s - A pandas Series object
import pandas as pd
import numpy as np

Importing data

pd.read_csv(filename) # From a CSV file
pd.DataFrame(dict) # From a dict, keys for column names, and values for data as lists

Viewing/inspecting data

df.head(n)
df.tail(n)
df.shape
df.info()
df.describe() # Summary statistics for numerical columns
df.isna().sum() # Sum of null values per col
df.notna()
s.value_counts(dropna=False) # View unique values and counts
df.value_counts(dropna=False, normalize=True,ascending=True)

Selection and reference

 # Slicing with [], work on rows
s[:5]
df[:5] # Return first 5 rows
df[::2]# Return dataframe with a step of 2 on row selection
df[::-1] # Return a reversed dataframe
 # Select columns and rows
df["col"] # Return the column as `Series`
df[["col"]] # Return the col as `DataFrame`
df[["col1","col2"]]
df[df['col1']>0] # Return the rows where the values of 'col1'>0
df[df['col1']>0]['col2'] # Return 'col2' on selected rows based on values of 'col1' as a Series
df[df['col1']>0][['col2']] # Return 'col2' on selected rows based on values of 'col1' as a DataFrame

 # Select by label via .loc[]
df.loc[0] #Return a Series for row 0
df.loc[[0]] #Return a DataFrame for row 0
df.loc[[0,3]] #Return a DataFrame -- the rows with integer index 0 and 3
df.loc[:5] # Return a DataFrame with rows index from 0 to 5 (note include index 5)
df.loc["row1":"row2"] # Return a DataFrame with rows index from "row1" to "row2"
df.loc[:5,"col1":"col2"] # Return a DataFrame with rows index from 0 to 5, columns index between "col1" and "col2"
df.loc[["a", "c"],"col2":] # Return a DataFrame with rows index "a" and "c", columns index from "col2" to the end
df.loc['a', 'A'] # Return a cell value at row "a", col "A"
df.loc[:,"col1"]>0 # Return a boolean type Series along rows
df.loc[df.loc[:,"col1"]>0,:] # Return rows selected by a boolen array
df.loc[df.col1>0,:] # Return rows selected by a boolen array, a simplified way
df.loc[lambda df: df.col1>0,:] # Selection by Callable lambda function
#lambda with .loc be more useful in complex operations or when chaining multiple methods together, as it allows you to pass functions dynamically.

df.loc[lambda df: (df.col1>0) & (df.col2=="2009-01-02"),:].assign(col3=lambda df: df.col1 - 2, col4=lambda df: df.col3*2)
#Select by position via .iloc[], integer based indexing
df.iloc[0] #Return a Series -- the first row
df.iloc[[0]] #Return a DataFrame
df.iloc[[0,3]] # Return 1st and 4th rows
df.iloc[:4, :4] # Return the top_left_corner (first four rows, and first four columns)
df.iloc[-4:, -4:] #Return the bottom right corner
df.iloc[[1, 3, 5], [1, 3]]
df.iloc[0,0] # Retrun the cell value at first row, first column

Data cleaning

 # Change column or index names
df.columns= ['new1', 'new2', 'new3'] # Rename columns
df.rename(columns={"old1":"new1","old2":"new2"}) # Selective renaming using a mapping
df.rename(index={0: "x", 1: "y", 2: "z"}) **#Rename index using a mapping**
df.rename(index=lambda x: x+1) # Mass renaming index
df.set_index("col_A") # Set the DataFrame index using existing column "col_A"
 # Dealing with null values
df.isna() #Return a boolean same-sized object
df["col1"].isna() # Return a boolean Series
df.notna() # opposite of .isna()
df.dropna() # Drop all rows that contain null values, default inplace=False
df.dropna(inplace=True) # Change inplace
df.dropna().reset_index() # Drops rows with null values and reset index
df.dropna(axis=1) # Drop columns that contain null values
df.dropna(how='all') # Drop rows when all elements are missing ; Default= "any" (at least one element is missing)
df.dropna(thresh=n) # Drop rows that have less than thresh n non-null values
df.fillna(x) # Replace all null values with x
df.fillna(value={"A": 0, "B": 1}) # Replace NaN in column 'A', 'B', with 0, 1 respectively.
s.fillna(s.mean()) # Replace NaN with mean
df.fillna(df.mean(axis=0)) # Fill NaN values with the mean of each column
df["col1"].fillna(df["col1"].mode()[0]) # Fill NaN values with the mode of the column**;** Note that .mode() here returns a Series object so use [0] to select the (first) element/value
 # Dealing with dulplicates
df.drop_duplicates(subset=['col1,col2'],keep='last')
 # Drop rows or columns
df.drop([0,1]) # Drop rows by index
df.drop(['A','B'], axis=1) # Drop columns
df[df['col1'] <= 2] # Drop rows where the values of "col1" >2
 # Change data type
s.astype(float) # Convert to float
 # Replace values
s.replace(1,"one") # Replace 1 with "one"
df.replace([1,3],["one","three"])
df.replace({1:"one", 3: "three"})

Filter, sort, groupby and transform

 # Filtering
df[df['col']>0.5] **# Select rows that meet the condition**
df[(df['col']>0.5) & (df['col']<1)]
df.loc[df['col']>0.5,:]
df.where(df>0.5) # Keeps the original values where the condition is True and replaces with np.nan where the condition is false
df.where(df>0.5, other=0) # replace with 0 where the condition is false
 # Sorting
df.sort_index() # Sort by index along rows in ascending order
df.sort_index(ascending=False, inplace=True) # Sort by index along rows in descending order, inplace change
df.sort_values(by="col",ascending=False) # Sort values by col in descending order;
df.sort_values(by=["col1','col2'],ascending=[False, True])
df.reset_index() # Reset index
df['col_rank']=df['col'].rank() # Creates a new column where each entry corresponds to the rank (1 through n) of that row's value in column 'col'
df['col_rank']=df['col'].rank(method='min',ascending=False) # the records that have the same values are ranked using the lowest rank; by default the average rank is used; other methods are **'max', 'first', 'dense'**.

 # Grouping
df.groupby('col') # Returns a groupby object for values from col; this did a mapping to df
df.groupby(['col1','col2'])
df.groupby('col').size() # Return the number of rows in each group
df.groupby('col').count() # Retrun the number of NON_NULL values for each column

df.groupby('col')['col2'].count() # Retrun the number of NON_NULL values for 'col2'
df.groupby('col').mean() # Produces a DataFrame with the group names as its new index and the mean values for each numeric column by group; other methods include **median(), mode(), sum(), size(), count(), min(), max(), std(), var(), describe() , nunique()**
df.groupby('col1')['col2'].mean() #Return the mean of the values in col2, grouped by the values in col1
df.groupby('col1')[['col2', 'col3']].mean() #Return the mean of the values in col2 and col3, grouped by the values in col1
df.groupby('col1')[['col2', 'col3']].agg(['sum', 'mean', 'std']) # Apply functions at once, using pandas' optimized groupby sum(), mean(), std()methods
df.groupby('col1').agg({"col2": "mean", "col3": "std"}) # Apply "mean" to "col2", "std" to "col3"
df.groupby('col1')['col2'].transform(lambda x: (x - x.mean()) / x.std()) # Rreturn a new DataFrame with the same row numbers and indexing as the original one but with transformed individual values
df.groupby('col1')['col2'].transform(lambda x: x.fillna(x.mode()[0]))
df.groupby('col1').head(n) # Returns the first n rows (5, by default) of each group correspondingly

 # Other transformation

df[['B', 'A']] = df[['A', 'B']] # Swap column contents
df.assign(name = ["Emil", "Tobias", "Linus"]) # Assign a new column "name" to a df, returning a new object with the new columns added to the original ones
df.assign(temp_f=lambda x: x.temp_c * 9 / 5 + 32) # Assign a new column "temp_f" from values of column "temp_c" via lambda function

 # use of .apply() on Series and DataFrames

df.apply(my_function) # Apply my_function to each column
df.apply(my_function, axis=1) # Apply my_function to each row
df['FirstName'] = df['EmployeeName'].apply(lambda x : x.split()[0]) # Apply lambda function on 'EmployeeName' col to create a new column
df['Value3']=df['Value1'].apply(lambda x: x2)**
mask=df.apply(lambda x: True if x ['Gender'] == 'F' and x['Kids'] > 0 else False, axis=1) # return a boolean Series
df['BMI'] = df.apply(lambda x: calc_bmi(x['Weight'], x['Height']), axis=1) # Apply the custom function calc_bmi to the data frame, across each row

 # PIVOT_TABLE

table=pd.pivot_table(df,index=['col','col2'],values=['col3','col4'],columns='col5', aggfunc='sum') # Create a pivot table that groups by 'col1' and 'col2'; by default, aggfunc='mean'

Join/Combine

pd.concat([df1,df2]) # Concatenate along rows, retain original index
pd.concat([df1,df2],join="inner",ignore_index=True) # Concatenate along rows and return only overlapping columns, reset index
pd.concat([df1,df2],axis=1) # Concatenate along columns (only work if the tables have the same height)
Note df.append() had been deprecated
pd.merge(left, right, on="key") # Inner join on "key" in both dataframes
pd.merge(left, right, how="left", on=["key1", "key2"]) # Left join on ["key1", "key2"] in left
pd.merge(left, right, left_on="key", right_index=True, how="left", sort=False) # Join DataFrame left's column "key" with DataFrame right's index
df1.merge(df2, left_on='lkey', right_on='rkey') # how="inner" by default
df1.join(df2, how="inner") # .join() joins on indexes by default, how="left" by default

Statistics and Some Common Operations

df.sum() # Defual axis=0, sum of columns
df.min()
df.max()
df.median()
df.mode() # Retruns the mode of each column, a Series or a DataFrame
df.std()
df.count() # Return the number of non-null values in each column
df.nunique() # number of unique values
df.corr() # Returns the correlation coefficients between columns
df.copy()
df.T # Transpose rows and cols
df.size # nrows* ncols; different to the .size() for groupby object
df.values # Get a numpy array for df

Datetime in Pandas

Create Pandas Timestamp object
date = pd.Timestamp('2013-01-01')
date2 = pd.Timestamp('2013-01-01 21:15:06')
date3 = pd.Timestamp('Sep 04, 1982 1:35.18')
Create a Period object
month = pd.Period('2013-01', freq='M')
Create a sequence of dates
dates=pd.date_range('2022-2-7', periods=7) # Return a fixed frequency DatetimeIndex. Each date in the DatetimeIndex instance is an instance of the Timestamp.
pd.date_range(start='1/1/2018', periods=5, freq='3ME') # 3 month end frequency, by default, freq='D'
Separate element of a Timestamp object from built-in attributes
year=date.year
month=date.month
day=date.day
hour=date.hour
month_name=date.month_name()
week_day=date.weekday() # Return the day of the week as a number, counting from 0 (for monday)
day_name=date.day_name()
Convert to a pandas datetime object
df['datetime'] = pd.to_datetime(df['datetime'],yearfirst=True) # Convert column 'datetime' (string object) to a datetime object
df['datetime'] = pd.to_datetime(df['datetime'], format="%y-%m-%d") # # Convert column 'datetime' (string object) to a datetime object by providing an exact format
mask = (df['datetime'] >= pd.Timestamp('2019-03-06')) & (df.datetime < pd.Timestamp('2019-03-07')) # Create a Boolean mask to select the DataFrame rows between two specific dates
df[mask]
df.set_index('datetime', inplace=True) # Set the datetime column as the index of the DataFrame for Timestamp slicing
df.loc['03-04-2019':'04-04-2019'] # Return rows within a date range.
